REPORT No. 331

COLLECTION OF WIND-TUNNEL DATA ON COMMONLY USED WING SECTIONS

By F. A. LOUDEN

SUMMARY

This report was prepared at the request of the National Advisory Committee for Aeronautics in the Bureau of Aeronautics of the Navy Department in order to group in a uniform manner the aerodynamic properties of commonly used wing sections as determined from tests in various wind tunnels.

The data have been collected from reports of a number of laboratories. Where necessary, transformation has been made to the absolute system of coefficients and tunnel wall interference corrections have been applied. Tables and graphs present the data in the various forms useful to the engineer in the selection of a wing section.

INTRODUCTION

The wing sections most commonly used in this country are the Clark Y, Clark Y-15, Gottingen G-387, G-398, G-436, N. A. C. A. M-6, M-12, Navy N-9, N-10, N-22, R. A. F.-15, Sloane, U. S. A.-27, U. S. A.-35A, U. S. A.-35B. Data were obtained from References 1 to 14 on all of these airfoils that had been tested in the following wind tunnels:

- Large wind tunnel, Göttingen Laboratory.
- Variable density wind tunnel, Langley Memorial Aeronautical Laboratory.
- 7½-foot wind tunnel, Massachusetts Institute of Technology.
- 5-foot wind tunnel, McCook Field.
- 8-by-8-foot wind tunnel, Washington Navy Yard.

Some of the airfoils selected had been tested in as many as four of the five tunnels, others in only one of the tunnels.

The results obtained in the different laboratories are not directly comparable, because of the differences in the methods of testing; in the ordinates, size, and aspect ratio of the models tested and in the test speed. The purpose of this report is not to compare results from different laboratories but to present the data in a uniform manner and to compare different wing sections tested in the same laboratory at the same Reynolds Number.

In the individual laboratory reports, the data in some cases were presented in engineering rather than absolute coefficients; in most cases, the tunnel wall interference corrections had not been applied; for some tests the center of pressure had not been determined; the moment coefficient was given with respect to various axes; the data were presented by some laboratories in polar diagrams and by others in angle-of-attack graphs.

In the present report the collected data have been corrected for tunnel wall interference, the absolute system of coefficients is used, and the data are plotted and tabulated in various forms for the convenience of the engineer.

ABSOLUTE SYSTEM OF COEFFICIENTS

The absolute lift and drag coefficients C_L and C_D are defined by dividing the lift L and the drag D by the dynamic pressure $q = \frac{1}{2} \rho V^2$ and the wing area S .

$$C_L = L/qS \quad C_D = D/qS.$$

The absolute moment coefficient C_M is the moment M about the leading edge divided by qS times the chord length c and is positive when the moment tends to make the leading edge rise.

$$C_M = M/qSc.$$

The center of pressure coefficient C_p is the fraction of the chord length along the chord from the leading edge to the line of action of the resultant force. This distance is equal to the moment coefficient divided by the normal force coefficient C_N .

$$C_p = C.P./c = C_M/C_N$$

where $C_N = C_L \cos \alpha + C_D \sin \alpha$.

The induced drag coefficient C_{D_i} is equal to C_L^2 divided by π times the aspect ratio.

$$C_{D_i} = C_L^2/\pi A.R. = C_L^2 S/\pi b^2$$

where b is the span.

The profile drag coefficient C_{D_0} is the difference between the coefficients of total drag and induced drag

$$C_{D_0} = C_D - C_{D_i}$$

TUNNEL WALL INTERFERENCE CORRECTIONS

A large share of the data taken from References 1 to 14 had not been corrected for tunnel wall interference. The following Prandtl corrections have been applied where necessary:

$$\Delta \alpha = \delta \frac{C_L S}{A} \text{ radians} \quad \Delta C_D = \delta \frac{C_L^2 S}{A}.$$

A is the cross-sectional tunnel area and δ is equal to 0.125 for a tunnel having a circular cross section. For a tunnel of square cross section, Glauert has shown that δ increases to 0.137.

ORDINATES OF THE AIRFOILS

Table I gives the general shape of the various wing sections. The faired ordinates used by the Bureau of Aeronautics have been given and are called the specified ordinates. These ordinates may be slightly different from those in general use as exact specifications for the various sections do not exist. For this reason, a wing section at one laboratory might be expected to vary to some extent from the same section at another laboratory. The variation becomes greater in the measured ordinates due to the different materials used in airfoil construction and different methods of measuring the ordinates.

The maximum thickness of the airfoils and their thickness for front and rear spar depths are given in Table II. Since the spar depths for a wing to be selected are approximately known, a glance at this table will limit the number of wings for further consideration.

TEST CONDITIONS

No attempt will be made in this report to describe the various wind tunnels or their methods of testing. Only the conditions for the tests selected will be given.

The Göttingen Laboratory tests were made on 20 by 100 centimeter (7.874×39.37 inches) models at a test speed of 30 meters (98.4 feet) per second. This gives a test Vl of 64.58 square feet per second, where l is taken as the chord length. Since the elements of air density and viscosity were not determined, the exact Reynolds Number of the tests is not known. Assuming air of standard density ρ and the coefficient of viscosity μ at standard temperature, $\rho/\mu = 6,378$ sq.ft./sec., and the approximate Reynolds Number $\rho Vl/\mu$ is 412,000.

The Langley Memorial Aeronautical Laboratory (L. M. A. L.) tests were made on 5 by 30 inch models at a test speed of approximately 76 feet per second. Tests on most of the models were made at several pressures, but only the tests at a pressure of about 20 atmospheres are considered here. The average Reynolds Number for each test was determined and is in the neighborhood of 3,600,000 corresponding to full-scale conditions.

The Massachusetts Institute of Technology (M. I. T.) tests were made on 6 by 36 inch models at a test speed of 40 miles an hour. The test V_l is 29.33 sq. ft./sec.; approximate Reynolds Number, 187,000.

The McCook Field (McC. F.) tests were made on 6 by 36 inch models at various air speeds. Only the tests at 80 miles an hour are considered here, giving a test V_l of 58.67 sq. ft./sec.; approximate Reynolds Number, 374,000.

The Washington Navy Yard (W. N. Y.) tests were made on 5 by 30 inch models at a test speed of 40 miles an hour; test V_l , 24.44 sq. ft./sec.; approximate Reynolds Number, 156,000.

With the exception of the Göttingen airfoils of aspect ratio 5, all of the models had the normal aspect ratio of 6. The experimental results of the Göttingen tests could be corrected to an aspect ratio of 6, but since the results from the different laboratories are not directly comparable, it was thought best to leave the data in the original form.

PRESENTATION OF DATA

The data from the Göttingen tests are given separately for each airfoil in Tables III to VI; L. M. A. L. tests, Tables VII to XIV; M. I. T. tests, Tables XV to XXII; McC. F. tests, Tables XXIII to XXV; W. N. Y. tests, Tables XXVI to XXXVII.

The usual C_L , C_D , and C_L/C_D versus angle of attack curves for the 15 wing sections are presented in Figures 1 to 15, and a table is inserted on each figure giving the test conditions. It might have been preferable to have plotted the data from each laboratory in one figure but this was not practical on account of the interference in the numerous curves.

In Figures 16 to 30 are plotted the Lilienthal polar diagrams, C_D and C_M versus C_L , together with the induced drag polar curves.

C_L/C_D is replotted against speed ratio V/V_s in Figures 31 to 45. The center of pressure is also plotted against speed ratio as the curves are approximately straight lines and are easier to read than the usual plots of center of pressure against angle of attack.

Graphs of the profile drag coefficient C_{D0} versus lift coefficient are presented in Figures 46 to 50. For these graphs it was possible to plot the data from each laboratory in one diagram and therefore the curves in each group are comparable. This same method is followed in Figures 51 to 55 which give the ratio of the faired profile drag coefficient to the maximum lift coefficient plotted against speed ratio.

AIRFOIL CHARACTERISTICS AND CRITERIA

Various characteristic values and criteria for the wing sections derivable from the data and graphs are tabulated in Tables XXXVIII to XLIX. When convenient, the tabulation of the criteria are made with respect to the merit of the wing section and a note to that effect is under the heading to the table.

The above-mentioned tables are self-explanatory and derivations of the criteria can be found elsewhere, but a few brief remarks regarding the meaning of some of the criteria appears desirable.

C_L maximum, Table XLI, is the criterion for minimum speed with a given wing loading or if the minimum speed is given, it is the criterion for the load which can be carried per unit area of wing.

The maximum ratio C_L/C_D , Table XLIII, is well known as a criterion for airfoil efficiency, greatest weight carried for a given thrust. It being also a criterion for maximum speed regardless of minimum, flattest glide, and maximum range. The value of C_L at maximum C_L/C_D is also tabulated and should be considered along with the maximum ratio of lift to drag. The ratio of lift to drag is given for various fractions of C_L maximum in Table XLIV. These data show the effectiveness for speed and climb.

The ratio of C_L maximum to C_D minimum, Table XLV, is the criterion for maximum speed with a given minimum. With constant loading, (C_L^2/C_D^2) maximum, Table XLVI, is an index of minimum power, maximum rate of climb, maximum ceiling, maximum duration; the ratio of C_L^2 maximum to C_D^2 minimum, Table XLVII, is the criterion for maximum speed range. For additional detail on the above-mentioned criteria, the reader is referred to Reference 15.

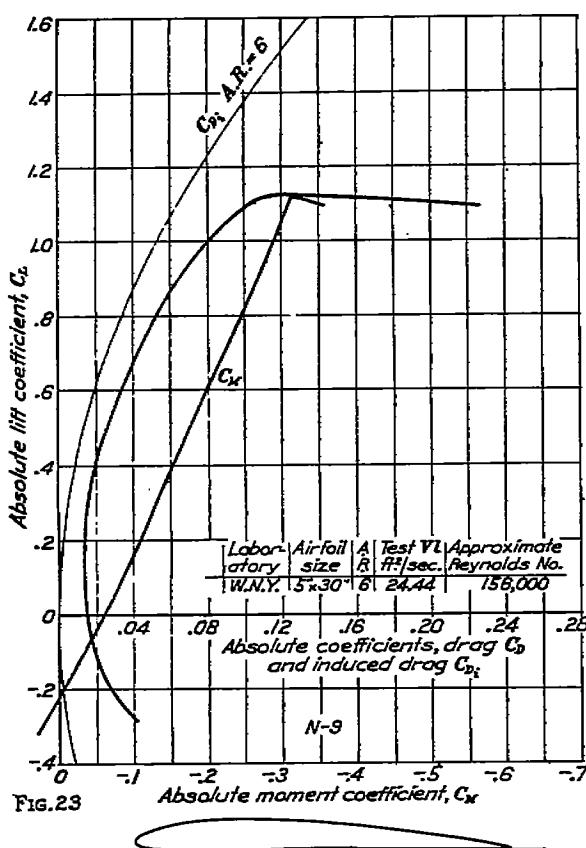

FIG. 23

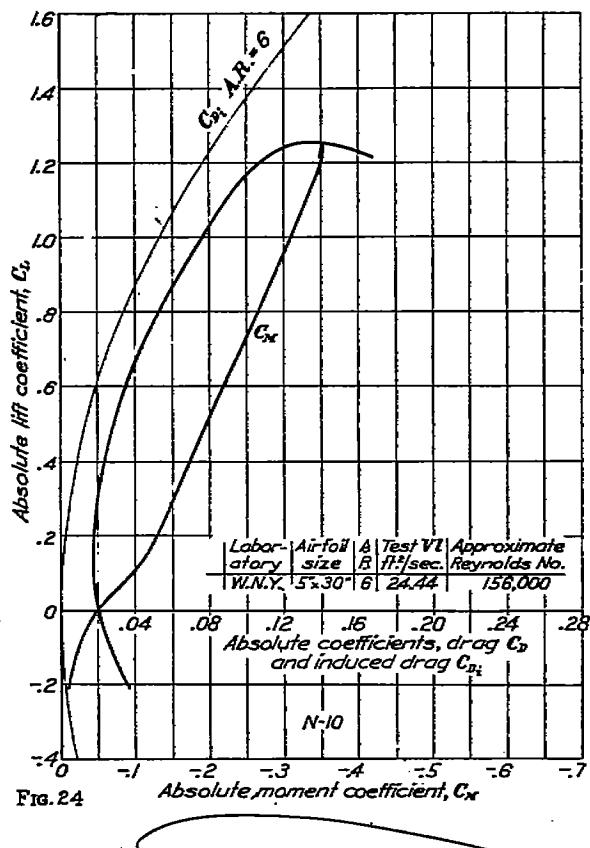

FIG. 24

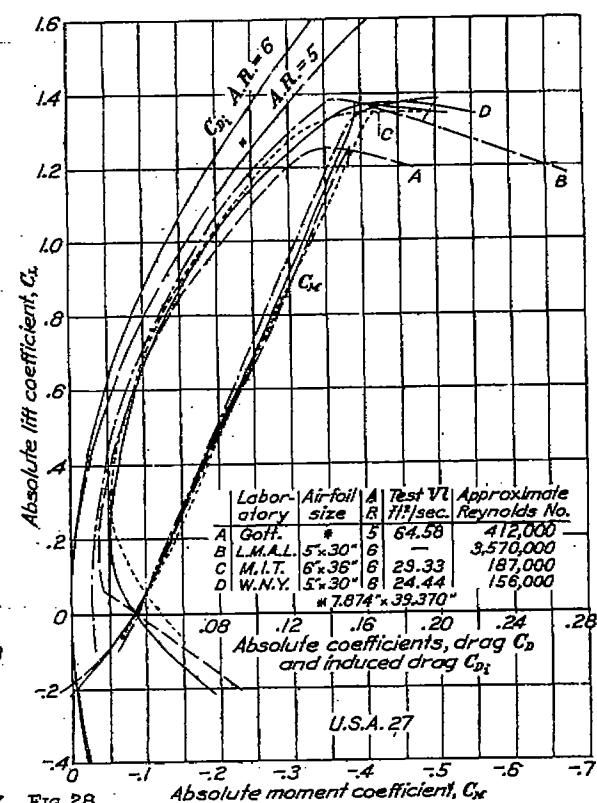

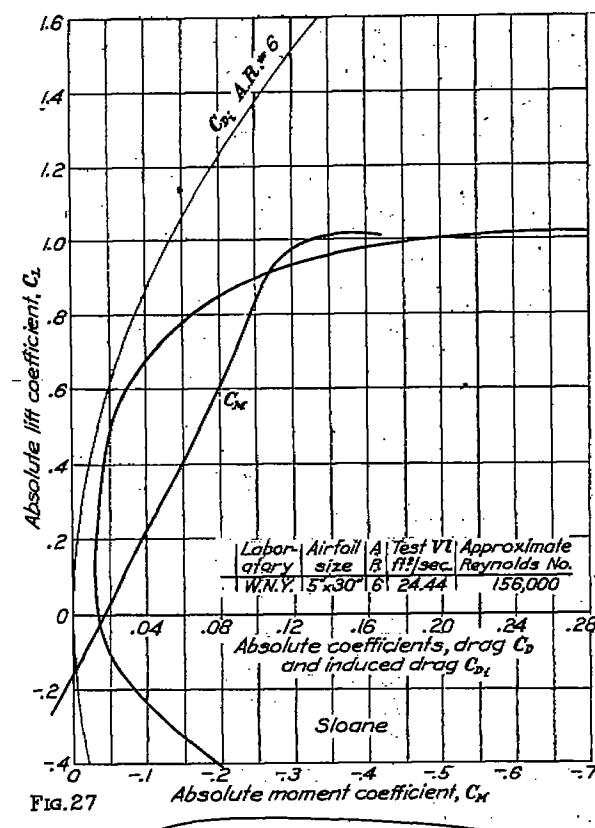

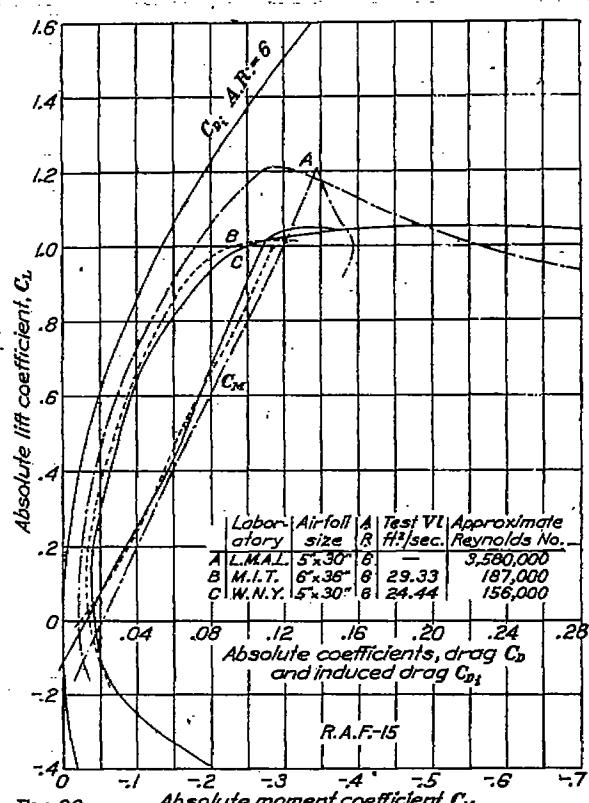

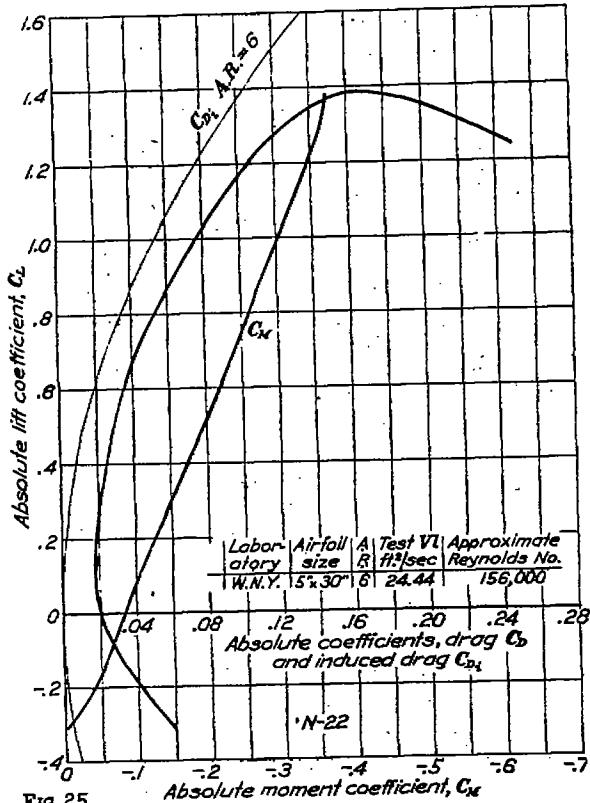

Table XLIX and Figures 51 to 55 compare the data on the basis of total profile drag for constant load and stalling speed. It is shown in Reference 16 that the section selected will vary with major requirements as follows:

Maximum speed.—Section having least value of C_{D_0}/C_L maximum at high speed ratios, $V/V_s > 2.5$.

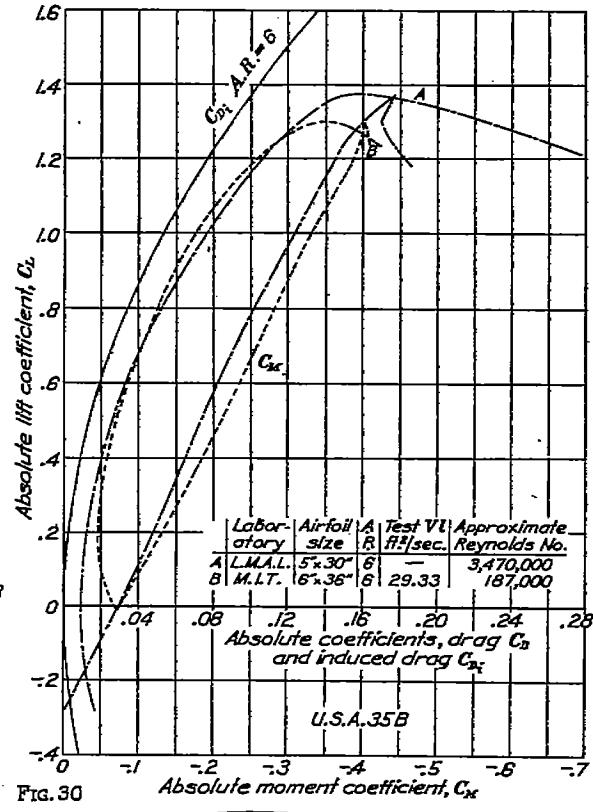

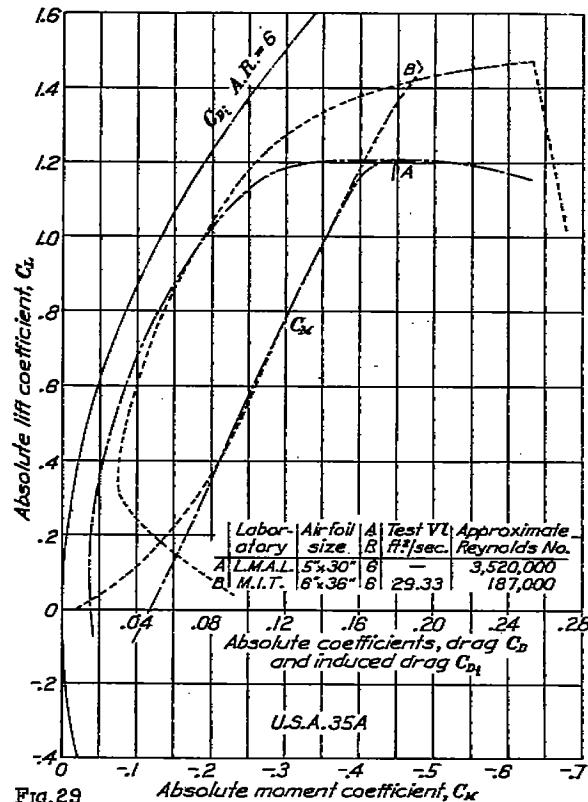

Maximum climb and ceiling.—Section having least value of C_{D_0}/C_L maximum between $V/V_s = 1.10$ and $V/V_s = 1.5$.

Maximum endurance.—Section having least value of C_{D_0}/C_L maximum at $V/V_s = 1.10$.

General performance.—Section having least average value of C_{D_0}/C_L maximum at all values of V/V_s .

SCALE EFFECT

The same conclusions regarding scale effect can be drawn from Figures 1 to 30 as have been drawn from previous test data. The following conclusions are quoted from Reference 17:

The scale effects depend on the airfoil section and are in general similar for similar sections.

All airfoil sections may be roughly divided into three general classes as follows:

(a) The highly cambered or very thick section having a very high lift at Reynolds Numbers within the testing range of the average wind tunnel. This class usually shows a decrease in C_L maximum with increase in Reynolds Number.

(b) The moderately cambered, medium lift section. This class usually has a moderate, and favorable scale effect on C_L with a fairly low and favorable scale effect on C_D .

(c) The thin, to moderately thick, double cambered section of low lift at normal test Reynolds Numbers. This class usually shows a large increase in C_L maximum and a moderate decrease in C_D minimum with increase in Reynolds Number.

Airfoils such as the G-387 and U. S. A.-35A come in class (a); the R. A. F.-15 and Clark Y in class (b); the M-6 and M-12 in class (c).

USE OF THE DATA

The diagrams and tables enable an engineer to make a logical selection of a wing section.

The full-scale data from the L. M. A. L. tests should be used whenever possible since free-flight tests have verified the validity of these data.

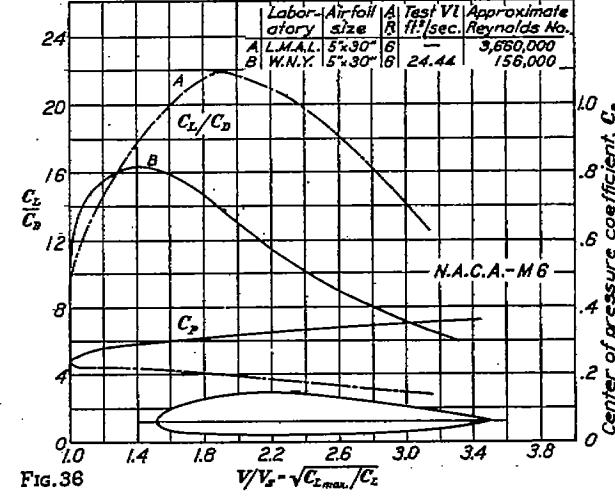

FIG. 36

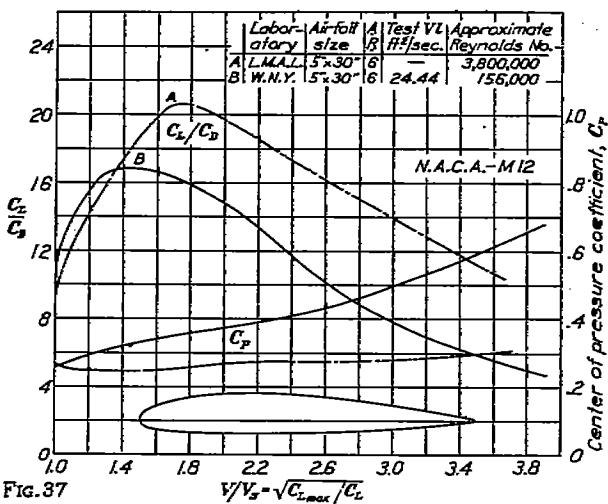

FIG. 37

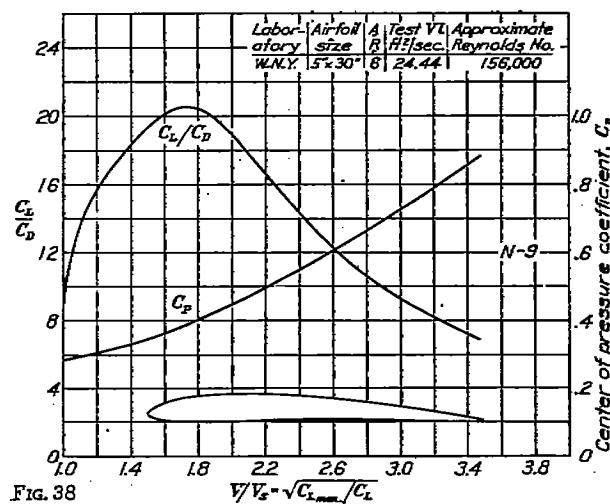

FIG. 38

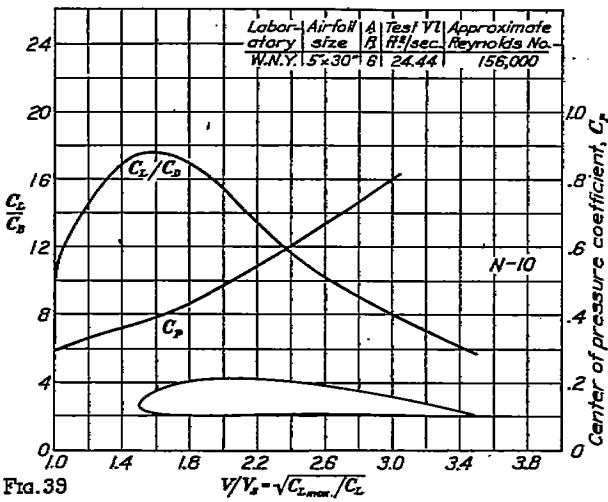

FIG. 39

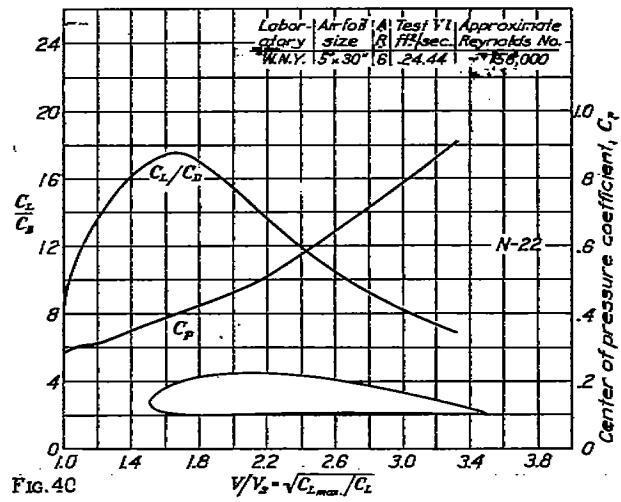

FIG. 40

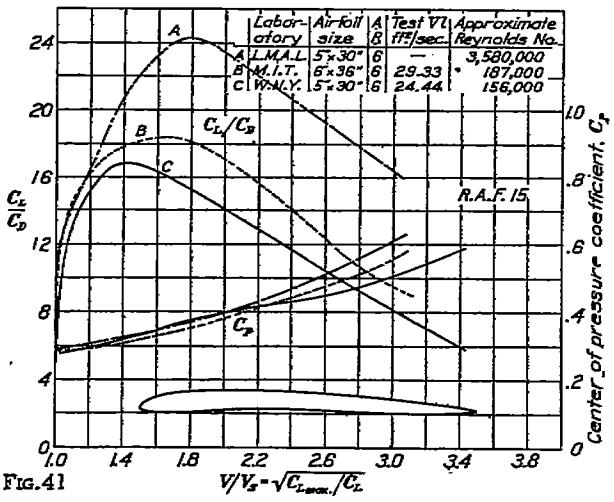

FIG. 41

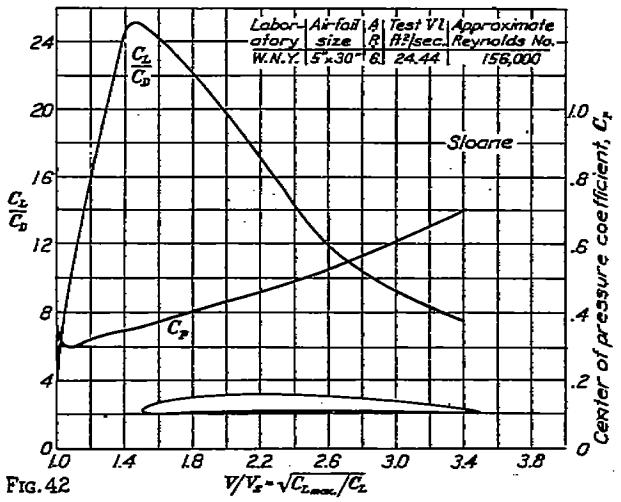

FIG. 42

Since the scale effect is in general similar for similar sections, it is to be expected that certain wing sections such as the G-398 and N-22 which show up well in an atmospheric tunnel would have good characteristics at full Reynolds Number. This has been verified by the flight test data on airplanes with these wing sections.

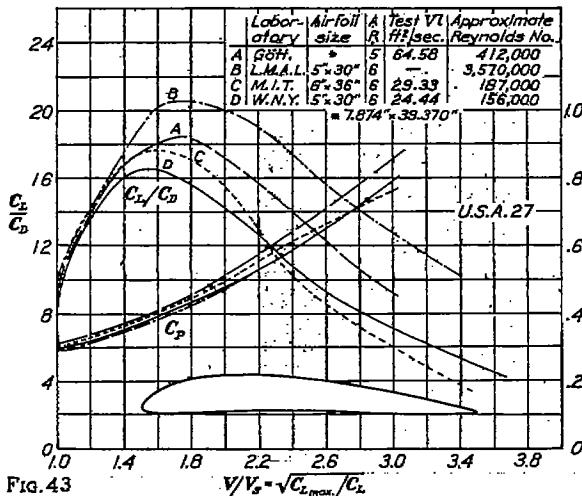

FIG. 43

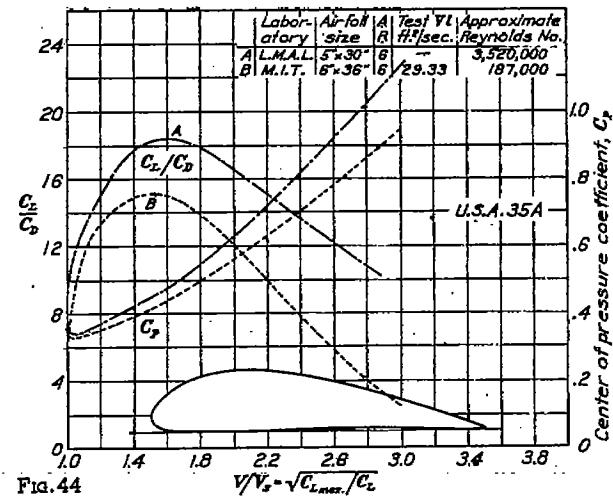

FIG. 44

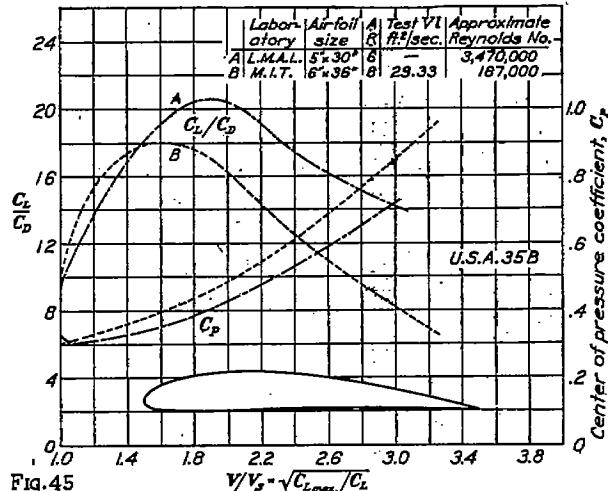

FIG. 45

CONCLUSIONS

The following conclusions can be drawn from this collection of airfoil data:

Direct comparison of the data should be made only when the Reynolds Numbers of the tests are the same. True relative values are then obtained at that Reynolds Number.

Allowance for the scale effect should be made when the tests are at different Reynolds Numbers.

The scale effect is in general similar for similar airfoil sections.

Test data at high Reynolds Numbers show better accord with free-flight data. Preference should therefore be given to data from the variable density tunnel.

More wings which show up well in an atmospheric tunnel should be tested at full scale. It is understood that this is now being done for a group of sections including the G-398.
